

# Concurrent Programming

15-213: Introduction to Computer Systems  
23<sup>rd</sup> Lecture, Nov. 17, 2015

## Instructors:

Randal E. Bryant and David R. O'Hallaron

# Concurrent Programming is Hard!

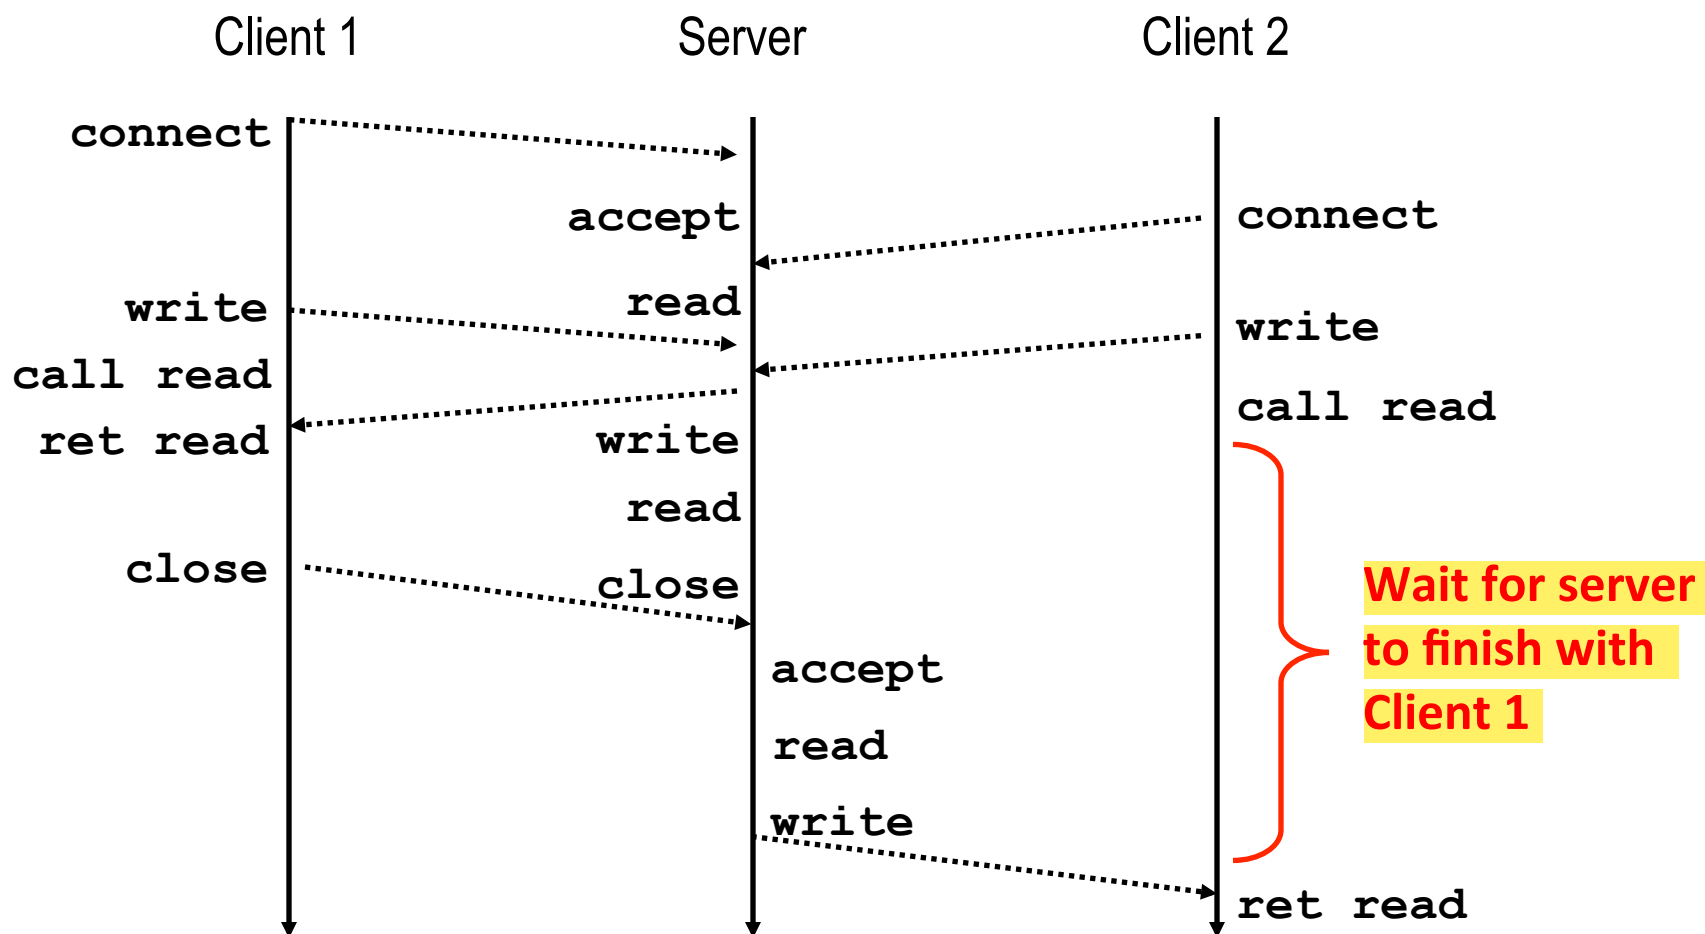

- The human mind tends to be sequential
- The notion of time is often misleading
- Thinking about all possible sequences of events in a computer system is at least error prone and frequently impossible

# Concurrent Programming is Hard!

- **Classical problem classes of concurrent programs:**
  - **Races:** outcome depends on arbitrary scheduling decisions elsewhere in the system
    - Example: who gets the last seat on the airplane?
  - **Deadlock:** improper resource allocation prevents forward progress
    - Example: traffic gridlock
  - **Livelock / Starvation / Fairness:** external events and/or system scheduling decisions can prevent sub-task progress
    - Example: people always jump in front of you in line
- **Many aspects of concurrent programming are beyond the scope of our course..**
  - but, not all 😊
  - We'll cover some of these aspects in the next few lectures.

# Iterative Servers

- Iterative servers process one request at a time

# Where Does Second Client Block?

- Second client attempts to connect to iterative server

- Call to `connect` returns

- Even though connection not yet accepted
- Server side TCP manager queues request
- Feature known as "TCP listen backlog"

- Call to `rio_writen` returns

- Server side TCP manager buffers input data

- Call to `rio_readlineb` blocks

- Server hasn't written anything for it to read yet.

# Fundamental Flaw of Iterative Servers

## ■ Solution: use *concurrent servers* instead

- Concurrent servers use multiple concurrent flows to serve multiple clients at the same time

# Approaches for Writing Concurrent Servers

Allow server to handle multiple clients concurrently

## 1. Process-based

- Kernel automatically interleaves multiple logical flows
- Each flow has its own private address space

## 2. Event-based

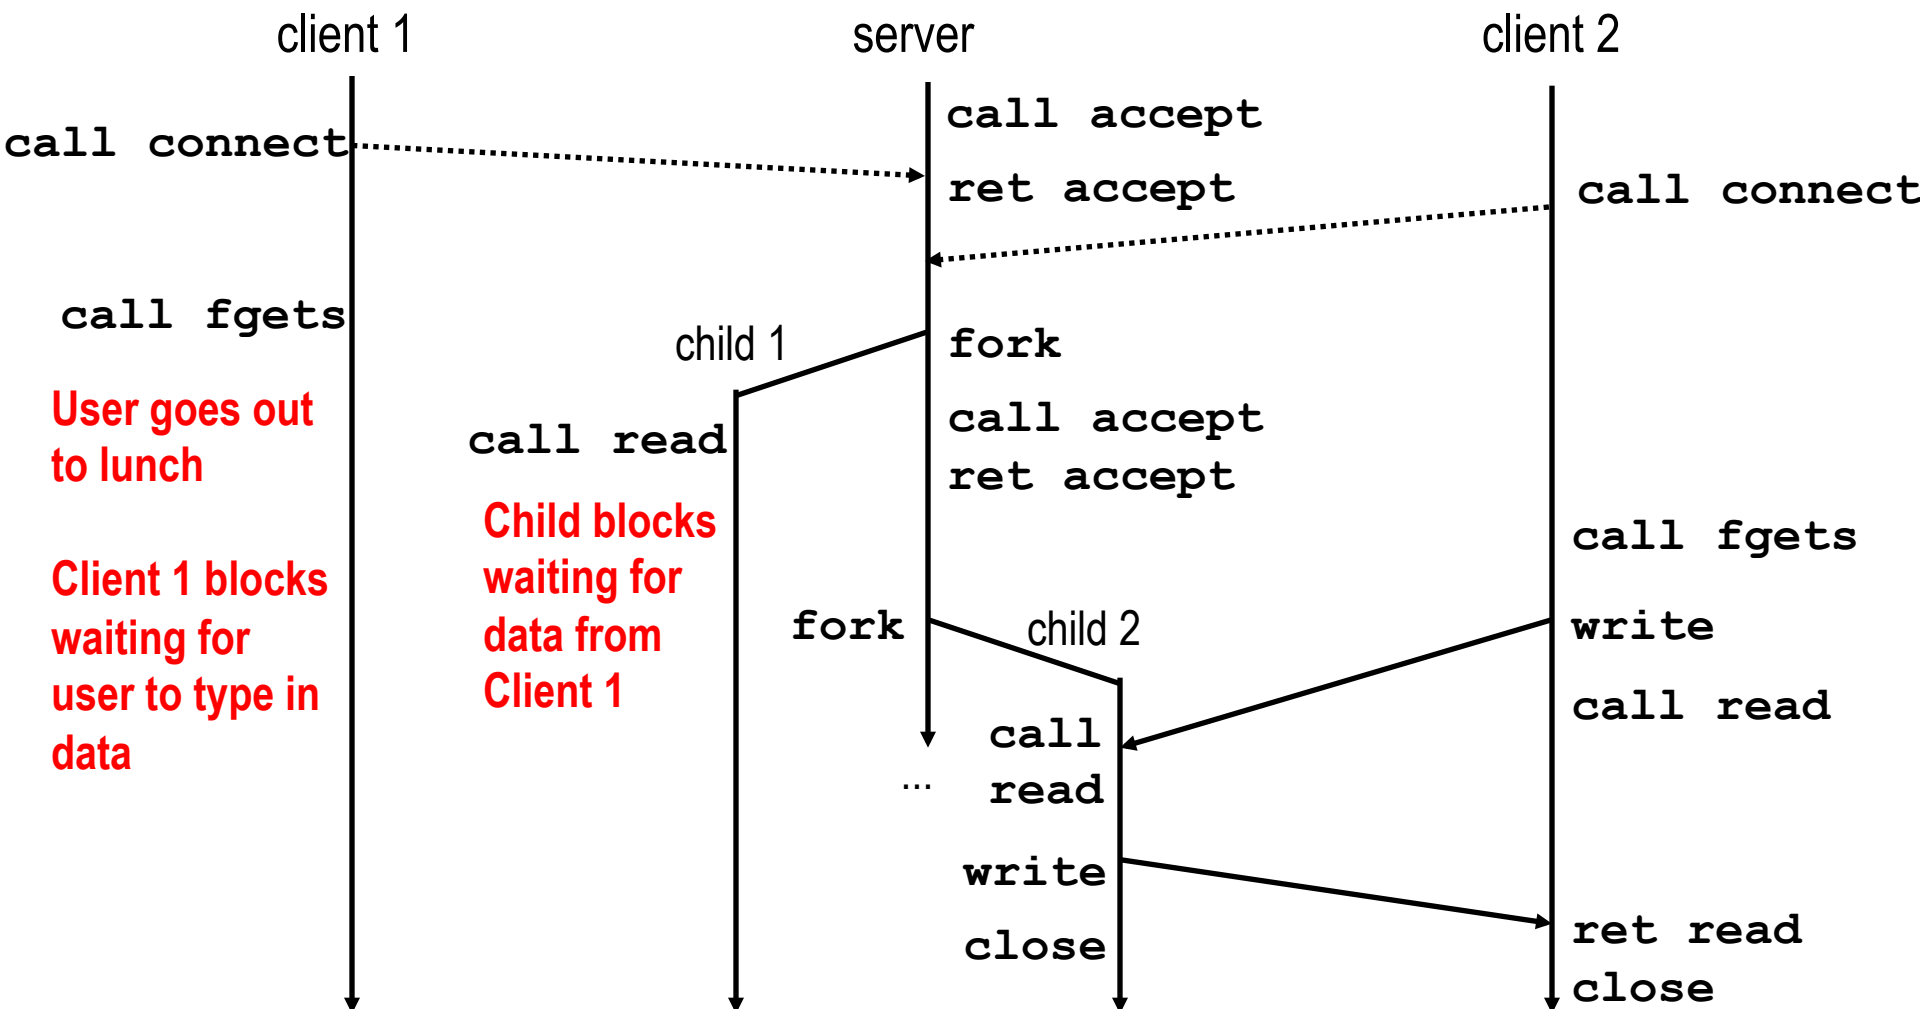

- Programmer manually interleaves multiple logical flows
- All flows share the same address space
- Uses technique called *I/O multiplexing*.

## 3. Thread-based

- Kernel automatically interleaves multiple logical flows
- Each flow shares the same address space
- Hybrid of of process-based and event-based.

## Approach #1: Process-based Servers

- **Spawn separate process for each client**

# Process-Based Concurrent Echo Server

```
int main(int argc, char **argv)
{
    int listenfd, connfd;
    socklen_t clientlen;
    struct sockaddr_storage clientaddr;

    Signal(SIGCHLD, sigchld_handler);
    listenfd = Open_listenfd(argv[1]);
    while (1) {
        clientlen = sizeof(struct sockaddr_storage);
        connfd = Accept(listenfd, (SA *) &clientaddr, &clientlen);
        if (Fork() == 0) {
            Close(listenfd); /* Child closes its listening socket */
            echo(connfd);    /* Child services client */
            Close(connfd);   /* Child closes connection with client */
            exit(0);         /* Child exits */
        }
        Close(connfd); /* Parent closes connected socket (important!) */
    }
}
```

echoserverp.c

# Process-Based Concurrent Echo Server (cont)

```
void sigchld_handler(int sig)
{
    while (waitpid(-1, 0, WNOHANG) > 0)
        ;
    return;
}
```

echoserverp.c

- Reap all zombie children

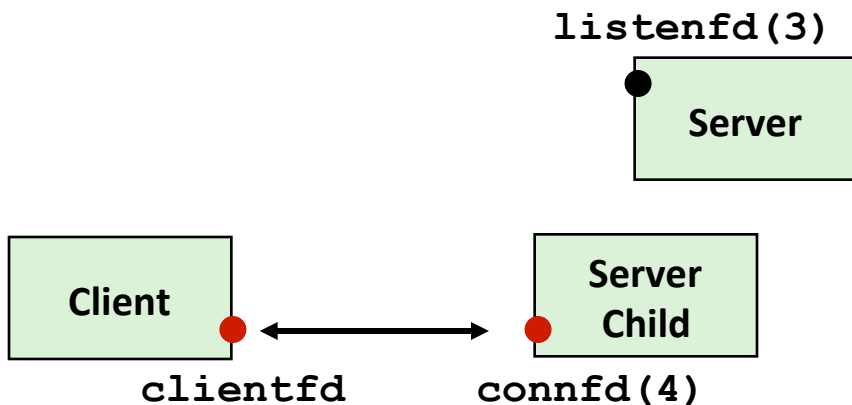

# Concurrent Server: `accept` Illustrated

1. **Server blocks in `accept`, waiting for connection request on listening descriptor `listenfd`**

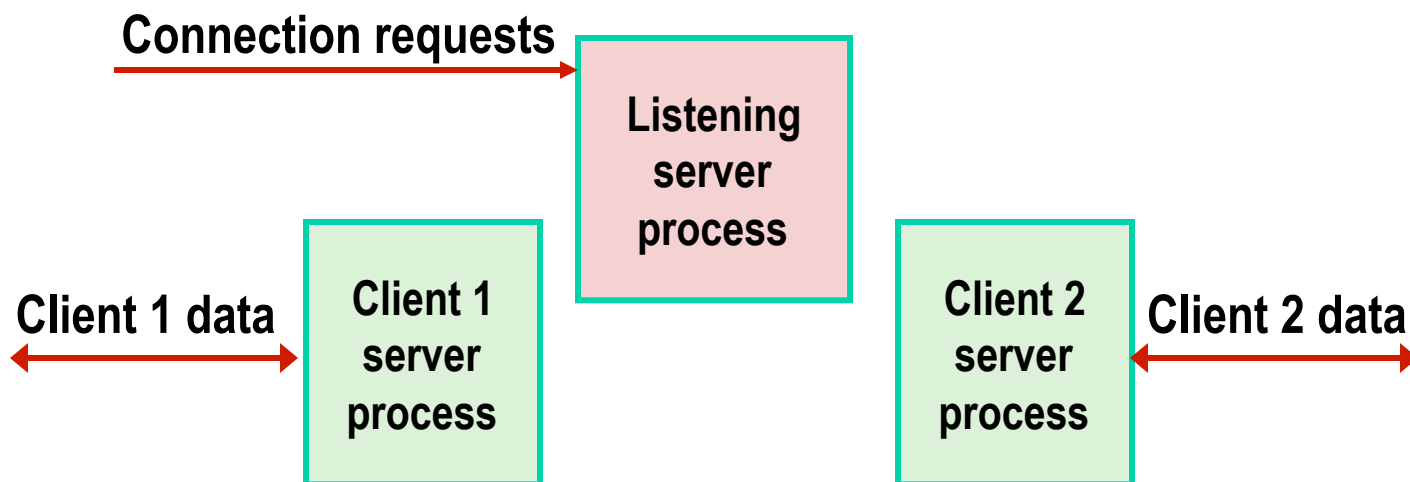

2. **Client makes connection request by calling `connect`**

3. **Server returns `connfd` from `accept`. Forks child to handle client. Connection is now established between `clientfd` and `connfd`**

# Process-based Server Execution Model

- Each client handled by independent child process
- No shared state between them
- Both parent & child have copies of `listenfd` and `connfd`
  - Parent must close `connfd`
  - Child should close `listenfd`

# Issues with Process-based Servers

- **Listening server process must reap zombie children**
  - to avoid fatal memory leak
- **Parent process must close its copy of connfd**
  - Kernel keeps reference count for each socket/open file
  - After fork, `refcnt(connfd) = 2`
  - Connection will not be closed until `refcnt(connfd) = 0`

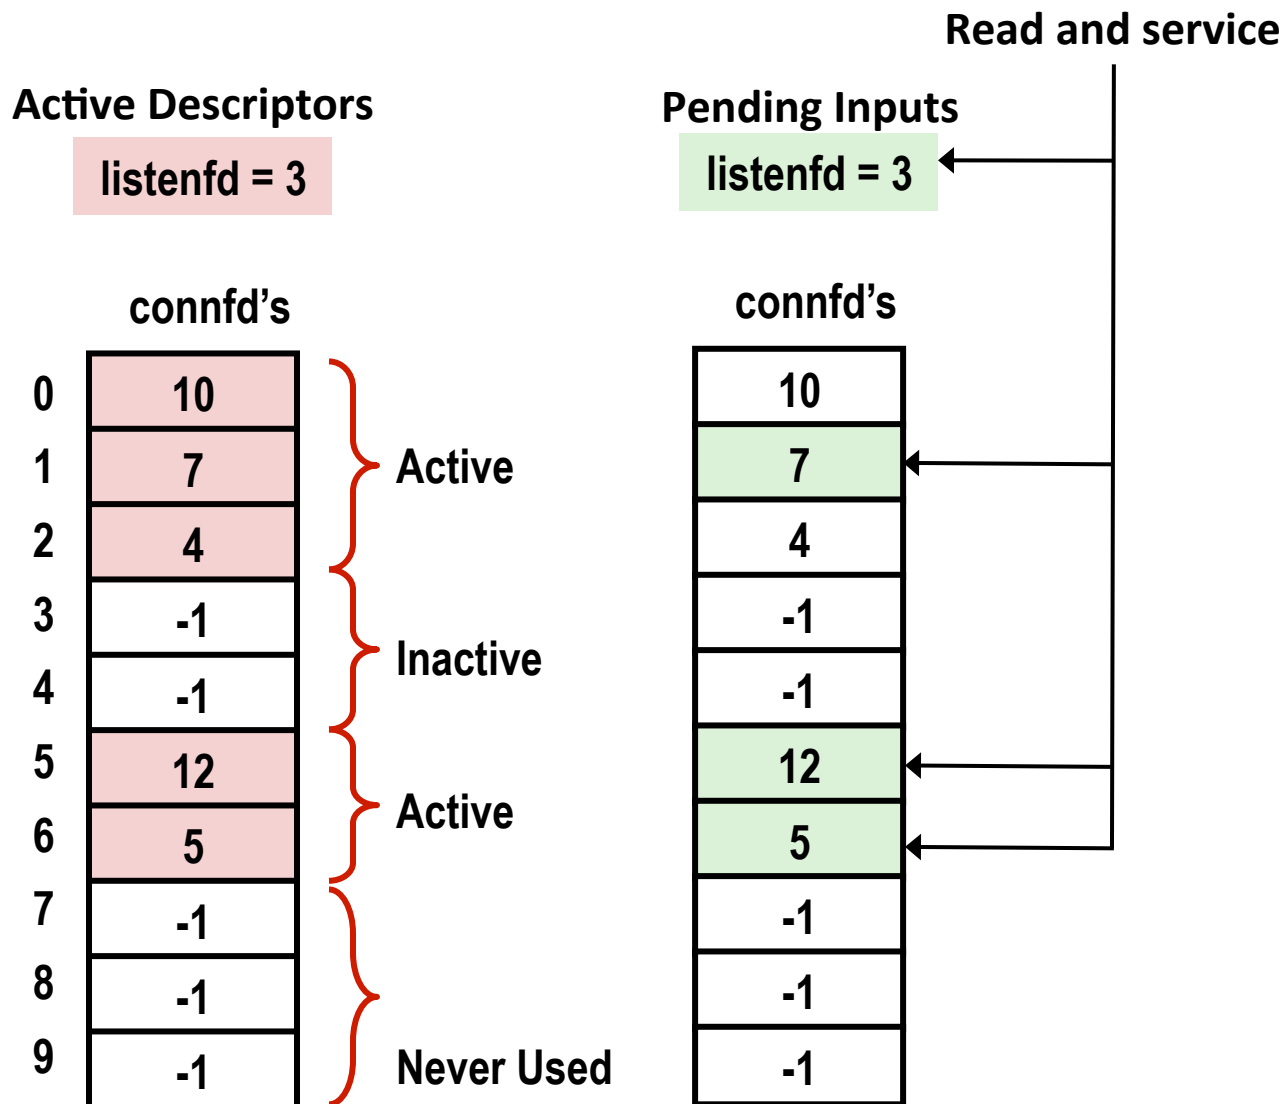

# Pros and Cons of Process-based Servers

- **+ Handle multiple connections concurrently**
- **+ Clean sharing model**
  - descriptors (no)
  - file tables (yes)
  - global variables (no)
- **+ Simple and straightforward**
- **– Additional overhead for process control**
- **– Nontrivial to share data between processes**
  - Requires IPC (interprocess communication) mechanisms
    - FIFO's (named pipes), System V shared memory and semaphores

# Approach #2: Event-based Servers

- **Server maintains set of active connections**
  - Array of `connfd`'s
- **Repeat:**
  - Determine which descriptors (`connfd`'s or `listenfd`) have pending inputs
    - e.g., using `select` or `epoll` functions
    - arrival of pending input is an *event*
  - If `listenfd` has input, then `accept` connection
    - and add new `connfd` to array
  - Service all `connfd`'s with pending inputs
- **Details for select-based server in book**

# I/O Multiplexed Event Processing

# Pros and Cons of Event-based Servers

- + One logical control flow and address space.
- + Can single-step with a debugger.
- + No process or thread control overhead.
  - Design of choice for high-performance Web servers and search engines. e.g., Node.js, nginx, Tornado
- – Significantly more complex to code than process- or thread-based designs.
- – Hard to provide fine-grained concurrency
  - E.g., how to deal with partial HTTP request headers
- – Cannot take advantage of multi-core
  - Single thread of control

# Approach #3: Thread-based Servers

- **Very similar to approach #1 (process-based)**
  - ...but using threads instead of processes

# Traditional View of a Process

- Process = process context + code, data, and stack

## Process context

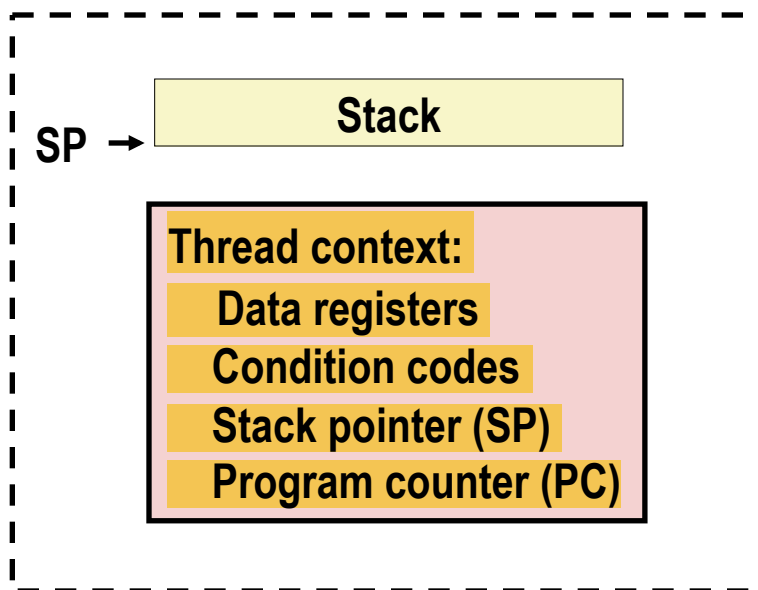

## Code, data, and stack

# Alternate View of a Process

- Process = **thread** + code, data, and kernel context

## Thread (main thread)

## Code, data, and kernel context

Kernel context:  
VM structures  
Descriptor table  
brk pointer

# A Process With Multiple Threads

- **Multiple threads can be associated with a process**
  - Each thread has its own logical control flow
  - Each thread shares the same code, data, and kernel context
  - Each thread has its own stack for local variables
    - but not protected from other threads
  - Each thread has its own thread id (TID)

**Thread 1 (main thread)**

**Thread 2 (peer thread)**

**Shared code and data**

**stack 1**

**stack 2**

Thread 1 context:  
Data registers  
Condition codes  
SP1  
PC1

Thread 2 context:  
Data registers  
Condition codes  
SP2  
PC2

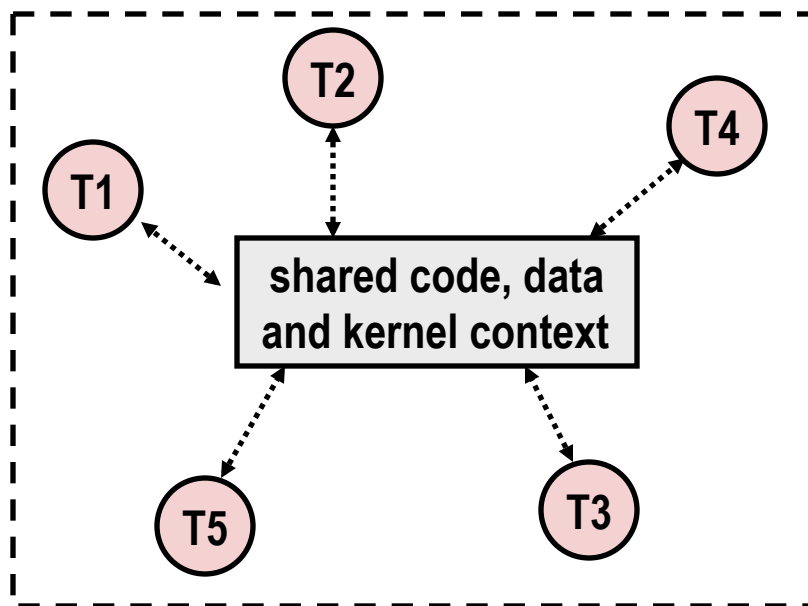

Kernel context:  
VM structures  
Descriptor table  
brk pointer

# Logical View of Threads

- **Threads associated with process form a pool of peers**
  - Unlike processes which form a tree hierarchy

Threads associated with process foo

Process hierarchy

# Concurrent Threads

- Two threads are *concurrent* if their flows overlap in time
- Otherwise, they are sequential

- **Examples:**

- Concurrent: A & B, A&C
- Sequential: B & C

Time

# Concurrent Thread Execution

## ■ Single Core Processor

- Simulate parallelism by time slicing

## ■ Multi-Core Processor

- Can have true parallelism

Run 3 threads on 2 cores

# Threads vs. Processes

## ■ How threads and processes are similar

- Each has its own logical control flow
- Each can run concurrently with others (possibly on different cores)
- Each is context switched

## ■ How threads and processes are different

- Threads share all code and data (except local stacks)
  - Processes (typically) do not
- Threads are somewhat less expensive than processes
  - Process control (creating and reaping) twice as expensive as thread control
  - Linux numbers:
    - ~20K cycles to create and reap a process
    - ~10K cycles (or less) to create and reap a thread

# Posix Threads (Pthreads) Interface

- ***Pthreads***: Standard interface for ~60 functions that manipulate threads from C programs
  - **Creating and reaping** threads
    - `pthread_create()`
    - `pthread_join()`
  - **Determining your thread ID**
    - `pthread_self()`
  - **Terminating threads**
    - `pthread_cancel()`
    - `pthread_exit()`
    - `exit()` [terminates all threads] , `RET` [terminates current thread]
  - **Synchronizing access to shared variables**
    - `pthread_mutex_init`
    - `pthread_mutex_[un]lock`

# The Pthreads "hello, world" Program

```
/*  
 * hello.c - Pthreads "hello, world" program  
 */
```

```
#include "csapp.h"
```

```
void *thread(void *vargp);
```

```
int main()  
{
```

```
    pthread_t tid;
```

```
    Pthread_create(&tid, NULL, thread, NULL);
```

```
    Pthread_join(tid, NULL);
```

```
    exit(0);  
}
```

hello.c

Thread ID

Thread attributes  
(usually NULL)

Thread routine

Thread arguments  
(void \*p)Return value  
(void \*\*p)

```
void *thread(void *vargp) /* thread routine */
```

```
{
```

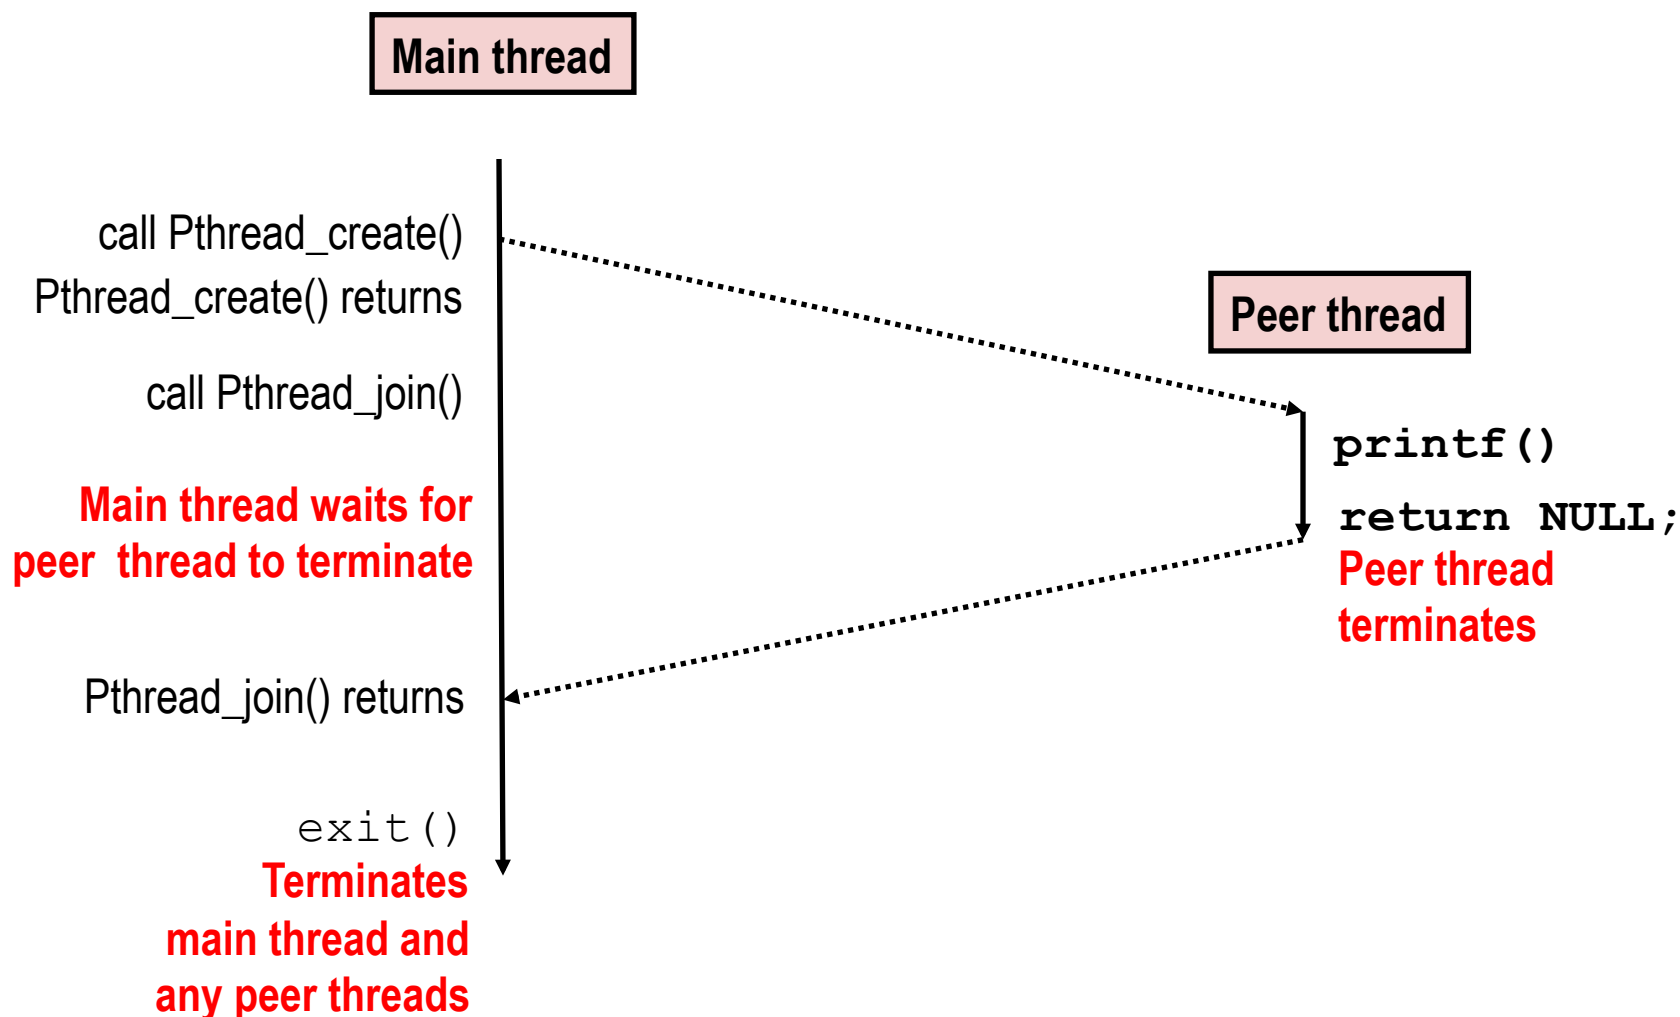

```
    printf("Hello, world!\n");
```

```
    return NULL;
```

```
}
```

hello.c

# Execution of Threaded “hello, world”

# Thread-Based Concurrent Echo Server

```
int main(int argc, char **argv)
{
    int listenfd, *connfdp;
    socklen_t clientlen;
    struct sockaddr_storage clientaddr;
    pthread_t tid;

    listenfd = Open_listenfd(argv[1]);
    while (1) {
        clientlen = sizeof(struct sockaddr_storage);
        connfdp = Malloc(sizeof(int));
        *connfdp = Accept(listenfd,
                          (SA *) &clientaddr, &clientlen);
        Pthread_create(&tid, NULL, thread, connfdp);
    }
}
```

echoserv.c

- malloc of connected descriptor necessary to avoid deadly race (later)

# Thread-Based Concurrent Server (cont)

```
/* Thread routine */  
void *thread(void *vargp)  
{  
    int connfd = *((int *)vargp);  
    Pthread_detach(pthread_self());  
    Free(vargp);  
    echo(connfd);  
    Close(connfd);  
    return NULL;  
}  
echoserv.c
```

- Run thread in “detached” mode.
  - Runs independently of other threads
  - Reaped automatically (by kernel) when it terminates
- Free storage allocated to hold `connfd`.
- Close `connfd` (important!)

# Thread-based Server Execution Model

- Each client handled by individual peer thread
- Threads share all process state except TID
- Each thread has a separate stack for local variables

# Issues With Thread-Based Servers

## ■ Must run “detached” to avoid memory leak

- At any point in time, a thread is either *joinable* or *detached*
- *Joinable* thread can be reaped and killed by other threads
  - must be reaped (with `pthread_join`) to free memory resources
- *Detached* thread cannot be reaped or killed by other threads
  - resources are automatically reaped on termination
- Default state is joinable
  - use `pthread_detach(pthread_self())` to make detached

## ■ Must be careful to avoid unintended sharing

- For example, passing pointer to main thread's stack
  - `Pthread_create(&tid, NULL, thread, (void *)&connfd);`

## ■ All functions called by a thread must be *thread-safe*

- (next lecture)

# Pros and Cons of Thread-Based Designs

- **+ Easy to share data structures between threads**
  - e.g., logging information, file cache
- **+ Threads are more efficient than processes**
- **– Unintentional sharing can introduce subtle and hard-to-reproduce errors!**
  - The ease with which data can be shared is both the greatest strength and the greatest weakness of threads
  - Hard to know which data shared & which private
  - Hard to detect by testing
    - Probability of bad race outcome very low
    - But nonzero!
  - Future lectures

# Summary: Approaches to Concurrency

## ■ Process-based

- Hard to share resources: Easy to avoid unintended sharing
- High overhead in adding/removing clients

## ■ Event-based

- Tedious and low level
- Total control over scheduling
- Very low overhead
- Cannot create as fine grained a level of concurrency
- Does not make use of multi-core

## ■ Thread-based

- Easy to share resources: Perhaps too easy
- Medium overhead
- Not much control over scheduling policies
- Difficult to debug
  - Event orderings not repeatable
